## TITLE OF THE INVENTION

## IMAGE FORMING APPARATUS

## BACKGROUND OF THE INVENTION

The present invention relates to an image forming  
5 apparatus for inputting an image to convert the input  
image into image data necessary for image formation,  
and more specifically, it relates to an image forming  
apparatus for performing a thinning process.

In a copying machine, printing rate is one of the  
10 factors that determine toner consumption per transfer  
paper. The printing rate is a value that is determined  
by the total area of printed objects in a copy image of  
a specific evaluation chart, and it is intimately  
concerned with the number of dots in an image formed by  
15 an image forming unit. Therefore, if the line of each  
letter or the like can be thinned by image processing,  
the number of dots in the image can be decreased. It  
is thus considered that thinning the lines by image  
processing to decrease the printing rate is effective  
20 for reduction of toner consumption.

Heretofore, thinning (line width control) has been  
performed after pseudo gradation processing such as  
error diffusion. As a discrimination method between an  
edge portion and a non-edge portion in an image, a  
25 matching process with a template pattern prepared in  
advance has been performed.

In the above-mentioned prior art, however, since

- 2 -

the target is binary image data after the gradation processing, discrimination accuracy is limited, and erroneous discrimination also occurs in places.

Therefore, if the degree of thinning is increased, a  
5 non-edge portion in a gradated photograph or the like may erroneously be discriminated as an edge portion and in such a case, an undesired influence occurs wherein the pixels in that portion are thinned. There is a problem that the degree of thinning can not  
10 sufficiently be increased to avoid such an influence. Besides, such an edge discrimination process by pattern matching requires a large amount of calculation and it is complicated. This causes another problem of an increase in circuit scale.

15 BRIEF SUMMARY OF THE INVENTION

An object of the present invention is to provide an image forming apparatus in which the discrimination accuracy of edge portions and so the effect of thinning can be increased without degrading the image quality by  
20 using, as a target to be processed, multi-value image data before gradation processing, and the hardware construction for the thinning process can be simplified by using a process in which an edge detection process with a filter is combined with the use of a  $\gamma$   
25 conversion table.

An image forming apparatus according to the present invention comprises an edge detection means for

detecting an edge in image data, a thinning judgment means for judging whether or not a thinning process in the image data should be performed, and an edge density conversion means for receiving a discrimination signal from the thinning judgment means to perform density conversion of a pixel which is judged to be subject to the thinning process.

Additional objects and advantages of the invention will be set forth in the description which follows, and in part will be obvious from the description, or may be learned by practice of the invention. The objects and advantages of the invention may be realized and obtained by means of the instrumentalities and combinations particularly pointed out hereinafter.

15 BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWING

The accompanying drawings, which are incorporated in and constitute a part of the specification, illustrate presently preferred embodiments of the invention, and together with the general description given above and the detailed description of the preferred embodiments given below, serve to explain the principles of the invention.

FIG. 1 is a block diagram of a general construction according to an embodiment of the present invention;

FIGS. 2A and 2B illustrate a thinning process according to the embodiment of the present invention;

- 5 -

first-order differential filter, the thinning judgment unit 11 performs filtering processes as described above in arbitrary directions of all the four directions, i.e., the main scanning direction, the auxiliary scanning direction, and two oblique directions. The thinning judgment unit 11 then uses, as an edge judgment discrimination signal, the OR value of the judgment results of those directions. FIG. 3 illustrates an example of the first-order differential filter.

In this embodiment, by varying the threshold for edge judgment, the area (pixels) judged to be an edge can be expanded or reduced and thereby the degree of thinning can be controlled. Further, in order to avoid degradation of image quality due to an excessive thinning process, the thinning judgment unit 11 detects a low-frequency area where the thinning judgment unit 11 does not perform the thinning process. This process will be referred to as a thinning control judgment. In the thinning control judgment, the maximum and minimum values in  $3 \times 3$  pixels of a target pixel and its peripheral eight pixels, and the differential value of them is calculated. The calculated differential value is then compared with a predetermined threshold. When the differential value is smaller than the threshold, the target area is considered a low-frequency (or low MTF) area and the target pixel is judged to be a

- 6 -

thinning control target (non-edge) pixel (signal value). The thinning judgment unit 11 uses the AND value of the edge judgment discrimination signal and the thinning control target judgment signal as a final  
5 thinning judgment discrimination signal ("1" in case of an edge and "0" in case of a non-edge).

FIGS. 2A and 2B illustrate a thinning process according to the present invention. The edge density conversion unit 12 performs an edge density conversion  
10 in accordance with the discrimination signal sent from the thinning judgment unit 11, as illustrated in FIGS. 2A and 2B. In this edge density conversion, a density conversion (in which the output density is lowered) is performed with a lookup table in relation  
15 to each pixel in an area 20 judged to be an edge. FIGS. 2A and 2B show states before and after the edge density conversion process, respectively.

In this embodiment, by varying set values in the lookup table, the degree of the thinning process can be  
20 controlled. The image signal to be subjected to the edge density conversion may not be the same as the signal input to the thinning judgment unit 11. For example, the target signal may have been subjected to the arbitrary image process 10 such as a smoothing  
25 process with an LPF (Low Pass Filter). Conversely, in the case of thickening, the lookup table is set so that the output density may be raised.
